

# TOT – Python Programming Essentials

**DAY 3 – CONTROL  
STRUCTURES (SELECTION)**

# TOPICS

**01** Control Structures

**02** Type Structures

**03** Sequence

**04** Selection

**05** Conditional Operators

**06** Compound Conditions

# CONTROL STRUCTURES

- A control structure (or flow of control) is a block of programming that analyses variables and chooses a direction in which to go based on given parameters.

- The basic decision-making process in programming and flow of control determines how a computer program will respond when given certain conditions and parameters.

# TYPES OF CONTROL STRUCTURES

## Sequential

Sequential execution is when statements are executed one after another in order. You don't need to do anything more for this to happen.

## Selection

Selection used for decisions, branching – choosing between 2 or more alternative paths.

## Iteration

Repetition used for looping, i.e. repeating a piece of code multiple times in a row.

# TYPES OF STRUCTURE {}

Sequence

Selection

Iteration

# SEQUENCE

The simplest structure

Control flows from one statement to the next

Statements are executed sequentially in the order in which they appear in the program

# EXAMPLE: SEQUENCE

A program that computes and prints the net pay of an employee contains the following code:

<code>grossPay = 20000</code>	<code># 1<sup>st</sup> statement to be executed</code>
<code>netPay = grossPay - 4000</code>	<code># 2<sup>nd</sup> statement to be executed</code>
<code>print("The net pay is: " + netPay);</code>	<code># 3<sup>rd</sup> statement to be executed</code>

# SELECTION

The selection statements are also known as decision making statements or branching statements.

Provides a choice between two alternatives

## 3 Components of the structure

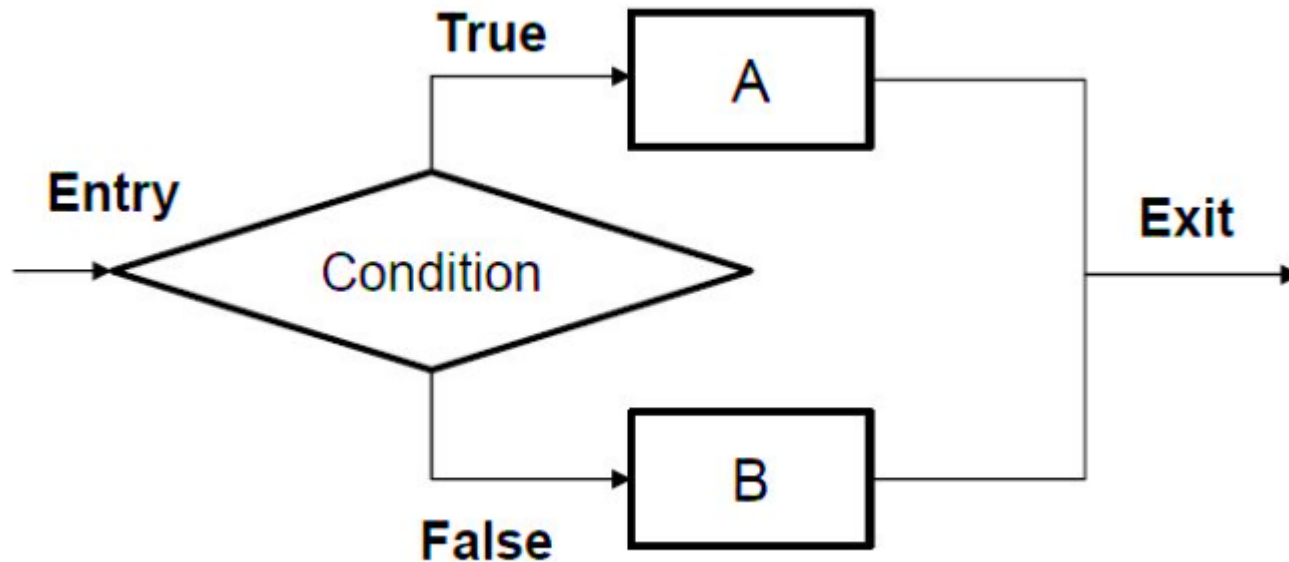

- A condition to be tested
- The statement to be performed if the condition is satisfied (process A)
- The statement to be performed if the condition is not satisfied (process B)

# SELECTION

- Entry to the structure is through the condition.

- Exit is through the execution of process A or process B

# SELECTION

---

Program code for single alternative selection:

```
if condition:  
    statement1
```

```
if condition:  
    statement1  
    statement2
```

where condition is a Boolean expression or Boolean variable

# SELECTION

---

Program code for multiple true selection:

```
if condition:  
    statement1  
elif condition:  
    statement2  
else:  
    statement3
```

# CONDITIONAL OPERATORS

❑ Equals:  $a == b$

❑ Not Equals:  $a != b$

❑ Less than:  $a < b$

❑ Less than or equal to:  $a <= b$

❑ Greater than:  $a > b$

❑ Greater than or equal to:  $a >= b$

# SOME COMMON ERRORS

Using `>` instead of `>=`

Example: "Write a program that would give customers over age 60 a discount of 20%"

- ☐ The phrase "over age 60" is not clear. Does it include the age 60 or not? Clarify what it means.
- ☐ Similar phrases that have unclear meaning are: "not more than", "at least", "not under".

# DAY 3

## ACTIVITY 1

- Write a program that will compute for the students average
- The user will input the following:
  - ☐ Name
  - ☐ Math
  - ☐ Science
  - ☐ English
- If the average is equal and above 75 status is Passed else You Failed the semester

Name: Vinz

Math: 80

Science: 90

English: 85

Average: 85.0

POSSIBLE OUTPUT:

Output 1:

Congratulations! You passed the semester. But you need to re-enroll English subject

Output 2:

Sorry, You Failed the semester

## DAY 3 ACTIVITY 1

# COMPOUND CONDITIONS

- ❑ Have more than 1 conditional expression
- ❑ The result of the compound expression depends on the individual result of each condition

Format:

`(condition1) and (condition2)`

`(condition1) or (condition2)`

# DAY 3

## ACTIVITY 2

- Write a program that will check the employees years in service and office.
- The user will input number for years and in service and the following offices (IT, ACCT, HR)
- Check the following conditions

Office	Years	
	more than or equal 10 years	below 10 years
IT	10000	5000
acct	12000	6000
hr	15000	7500

## DAY 3 ACTIVITY 2

# BUILT-IN METHODS

- ❑ `isupper()` - Returns True if all characters in the string are upper case
- ❑ `islower()` - Returns True if all characters in the string are lower case
- ❑ `isdigit()` - Returns True if all characters in the string are digits
- ❑ `isalpha()` - Returns True if all characters in the string are in the alphabet
